Petroleum Refining and Petrochemical Processes

Production of Olefins – Steam Cracking of Hydrocarbons

Ante Jukić

Steam cracking (pyrolysis) of hydrocarbons

Pyrolysis of hydrocarbons is the most important process of petrochemical production. It presents the main source for the majority of basic organic industrial raw materials:

α-olefin (ethene, propene, isobutene, butene), butadiene
and aromatic hydrocarbons (BTX = benzene, toluene, xylene)

Pyrolysis is non-catalyzed process of thermal decomposition of hydrocarbons. It is performed at very high temperatures, 750 - 900 °C, at approximately normal pressure.

Mainly cracking reactions of one or more covalent carbon-carbon bonds in the hydrocarbon molecules take place, under these conditions, by a free radical mechanism. Consequently, a larger number of smaller molecules is formed. At the same time reaction of dehydrogenation is going on, by cracking the carbon-hydrogen bond.

\[
\begin{align*}
C_nH_{2n+2} & \xrightarrow{\Delta} C_mH_{2m+2} + C_qH_{2q} & \text{cracking of } C-C \text{ bond} \\
\text{alkane} & \quad \text{alkane} \quad \text{alkene} \\
C_nH_{2n+2} & \xrightarrow{\Delta} C_nH_{2n} + H_2 & \text{cracking of } C-H \text{ bond} \\
\text{alkane} & \quad \text{alkene} \quad \text{hydrogen}
\end{align*}
\]

Both reactions lead to α-olephyne formation, the basic products of the process.
- side reactions:
isomerization, cyclization, polymerization and series of reactions of
cyclodehydrogenation → formation of coke (polyaromatic CH)

- the water steam is added to the feed - decreases the formation of side products
  → steam cracking.

The process is not catalytic; at lower temperatures olefins, dienes and aromatic
hydrocarbons are prone to the reactions of cyclization and formation of coke which
would be settled down on the surface of the catalyst and therefore very quickly
stopped its activity.

High temperature enables the reaction to be carried out in a very short time,
the retention time in the reactor (reaction furnace) in the range from 0.1 · · · 10 s,
depending on the feedstock.

This prevents a higher proportion of side reactions, especially the formation of coke.
Process of pyrolysis (steam cracking) of hydrocarbons results with $\alpha$-olefins as basic products whereat the overall products are:

The highest yield of ethylene is obtained by the dehydrogenation (pyrolysis) of ethane (80%), but due to insufficient quantity, the raw materials in the production of olefins usually are: 

- **naphtha**, obtained by direct distillation of crude oil,
- **propane-butane mixture** (LPG)
- and, rarely, **gas oil**.

**Natural gas condensate** is also used as raw material.
Production:
2012 = more than $100 \cdot 10^6$ t ethylene and more than $60 \cdot 10^6$ t propylene in pyrolytic plats (furnaces) of unit capacity of do $1 \cdot 10^6$ t / year of ethylene.

Methane and hydrogen are separated and commonly used as a feedstock in other processes or as fuel for the reactor - pyrolytic furnace. The resulting ethane, propane and part of non-reacted initial hydrocarbons are returned into the process.

Olefinic and aromatic hydrocarbons are the starting materials for the vast majority of (about 75%) organic chemical products. Therefore, pyrolysis of hydrocarbons is a basic process of petrochemical and organic chemical industry.
Schematic representation of the pyrolysis of hydrocarbons with water steam:

Raw materials:
- Ethane
- Propane
- Butane
- Naphtha
- Gas condensate
- Gas oil

Pyrolysis process:
- Temperature: 750...900 °C
- Pressure: 2...4 bar
- Water vapor: ≥ 40%
- Retention time: 1 s
- Conversion per pass: 60...80%

Separation of products:
- Cooling up to 300 °C
- Separation of CO₂, H₂S, H₂O
- Cooling (liquid methane)
- Low temperature fractionation

Products:
- Ethylene
- Propylene
- C4 hydrocarbons
- Pyrolysis gasoline
- Methane
- Hydrogen

Mechanism and reaction kinetics

Thermal decomposition by free radical chain mechanism

\[ \text{R - C : C - R}_1 \xrightarrow{\Delta} \text{R - C}^* \cdot \text{C - R}_1 \]

Formation of olefin hydrocarbons:

1. C–C bond cleavage

\[ \text{CH}_3\text{-CH}_2\text{-CH}_3 \xrightarrow{\Delta} \text{CH}_2\text{=CH}_2 + \text{CH}_4 \]

2. C–H bond cleavage (dehydrogenation)

\[ \text{CH}_3\text{-CH}_2\text{-CH}_3 \xrightarrow{\Delta} \text{CH}_3\text{-CH=CH}_2 + \text{H}_2 \]
Chain reaction of thermal decomposition of hydrocarbon by mechanism of free radicals comprise at least three basic reactions:

(1) *Initiation* or start of a reaction
(2) *Propagation* or reaction advancement
(3) *Termination* or reaction stop, and very often also
(4) *Transfer* of chain reaction.

Reactions mechanism and products of pyrolytic decomposition mainly depend on the type of hydrocarbon.
**Initiation:** breaking of C–C bonds occurs at elevated temperatures, with the formation of radicals of various molecular weights, e.g.:

\[
\text{CH}_3(\text{CH}_2)_6\text{CH}_3 \rightarrow \text{C}_5\text{H}_{11}\cdot + \text{C}_3\text{H}_7\cdot
\]

**Propagation:** Free radicals of higher molecular weight, short-term stable under conditions of pyrolysis, easily break by breaking C-C bonds in free radicals, usually in $\beta$-position ($\beta$-bond rule):

\[
\begin{align*}
\text{CH}_3-\text{CH}_2-\text{CH}_2^+ \underbrace{\text{CH}_2}^\beta \hat{\text{CH}}_2 & \overset{\alpha}{\Rightarrow} \text{CH}_3-\text{CH}_2^+ \text{CH}_2 \hat{\text{CH}} - \text{CH}_3 \\
\downarrow \beta\text{-scission} \quad & \quad \downarrow \beta\text{-scission} \\
\text{CH}_3^+ \text{CH}_2^- \hat{\text{CH}}_2 + \text{CH}_2=\text{CH}_2 & \quad \text{CH}_3^- \hat{\text{CH}}_2 + \text{CH}_2=\text{CH}=\text{CH}_3 \\
\downarrow \quad & \quad \downarrow \\
\hat{\text{CH}}_3 + \text{CH}_2=\text{CH}_2 & \quad \text{CH}_2=\text{CH}_2 + \text{H}^\cdot
\end{align*}
\]
The formation of the "new" radicals depends on the position of hydrogen atom (primary, secondary, tertiary).
The reaction of methyl radicals and propane, the most probable are the following reactions:

\[
\begin{align*}
\ce{CH3-CH2-CH3 + .CH3 &<-> CH3-CH-CH3 + CH4} \\
\ce{CH3-CH2-CH3 + .CH3 &<-> CH3-CH2-CH2 + CH4}
\end{align*}
\]

**Termination:**
The increasing concentration of free radicals leads to their mutual reaction and the formation of inactive molecules:

\[
\ce{R' + R_1' \xrightleftharpoons[k_t]{k_t} R-R_1}
\]
Pyrolytic decomposition of ethane

a) initiation: \[ \text{CH}_3\text{-CH}_3 \rightarrow 2 \cdot \text{CH}_3 \]

b) propagation:
\[ \cdot \text{CH}_3 + \text{CH}_3 \rightarrow \text{CH}_3 \cdot \text{CH}_2 + \text{CH}_4 \]
\[ \text{CH}_3 \cdot \text{CH}_2 \rightarrow \text{CH}_2=\text{CH}_2 + \text{H}^* \]
\[ \text{H}^* + \text{CH}_3\text{-CH}_3 \rightarrow \text{CH}_3 \cdot \text{CH}_2 + \text{H}_2 \]

c\text{,} \text{1}}) \text{ termination by combination:}
\[ 2 \cdot \text{CH}_3 \rightarrow \text{CH}_3\text{-CH}_3 \]
\[ \cdot \text{CH}_3 + \cdot \text{CH}_2\text{-CH}_3 \rightarrow \text{CH}_3\text{-CH}_2\text{-CH}_3 \]

c\text{,} \text{2}}) \text{ termination by disproportionation:}
\[ \cdot \text{CH}_2\text{-CH}_3 + \cdot \text{CH}_3 \rightarrow \text{CH}_2=\text{CH}_2 + \text{CH}_4 \]

Main products: *ethylene, hydrogen, methane*
Pyrolytic decomposition of propane

\[
\text{CH}_3\text{CH}_2\text{CH}_3 \rightarrow \text{CH}_3\text{CH}_2^\cdot + \text{CH}_3^\cdot
\]

\[
\text{CH}_3\text{CH}_2^\cdot + \text{CH}_3\text{CH}_2\text{CH}_3 \rightarrow \text{CH}_3\text{CH}_3 + \text{CH}_3\text{C}^\cdot \text{HCH}_3 \text{ (ili CH}_3\text{CH}_2\text{CH}_2^\cdot\text{)}
\]

\[
\text{CH}_3^\cdot + \text{CH}_3\text{CH}_2\text{CH}_3 \rightarrow \text{CH}_4 + \text{CH}_3\text{C}^\cdot \text{HCH}_3 \text{ (ili CH}_3\text{CH}_2\text{CH}_2^\cdot\text{)}
\]

\[
\text{CH}_3\text{CH}_2\text{CH}_2^\cdot \rightarrow \text{CH}_2=\text{CH}_2 + \text{CH}_3^\cdot
\]

\[
\text{CH}_3\text{C}^\cdot \text{HCH}_3 \text{ (ili CH}_3\text{CH}_2\text{CH}_2^\cdot\text{)} \rightarrow \text{CH}_3\text{CH}=\text{CH}_2 + \text{H}^\cdot
\]

\[
\text{H}^\cdot + \text{CH}_3\text{CH}_2\text{CH}_3 \rightarrow \text{H}_2 + \text{CH}_3\text{C}^\cdot \text{HCH}_3 \text{ (ili CH}_3\text{CH}_2\text{CH}_2^\cdot\text{)}
\]

\[
\text{C}_2\text{H}_5^\cdot \rightarrow \boxed{\text{CH}_2=\text{CH}_2} + \text{H}^\cdot
\]

\[
\text{CH}_3\text{C}^\cdot \text{HCH}_3 \text{ (ili CH}_3\text{CH}_2\text{CH}_2^\cdot\text{)} + \text{CH}_3^\cdot \rightarrow \boxed{\text{CH}_3\text{CH}=\text{CH}_2} + \text{CH}_4
\]
Dependence of reaction rate of thermal decomposition of alkanes on temperature and molecule size

![Graph showing the dependence of reaction rate on temperature and molecule size for ethane, n-pentane, propane, and n-butane.](image)
Alkenes

- not present in feedstock

- decompose similar to alkanes
  (large hydrocarbon molecules are broken down into smaller - reduction of molar mass)

- low temperatures & high pressure → polymerization
Cycloalkanes and aromatic hydrocarbons

**Process of Steam Cracking**

Steam cracking is a petrochemical process in which saturated hydrocarbons are broken down into smaller, often unsaturated, hydrocarbons. It is the principal industrial method for producing the lighter alkenes (or commonly olefins), including ethene (or ethylene) and propene (or propylene). Steam cracker units are facilities in which a feedstock such as naphtha, liquefied petroleum gas (LPG), ethane, propane or butane is thermally cracked through the use of steam in a bank of pyrolysis furnaces to produce lighter hydrocarbons.

The products obtained depend on the composition of the feed, the hydrocarbon-to-steam ratio, and on the cracking temperature and furnace residence time.

In steam cracking, a gaseous or liquid hydrocarbon feed like naphtha, LPG or ethane is diluted with steam and briefly heated in a furnace without the presence of oxygen. Typically, the reaction temperature is very high, at around 850 °C, but the reaction is only allowed to take place very briefly. In modern cracking furnaces, the residence time is reduced to milliseconds to improve yield (to avoid undesirable overcracking – formation of coke), resulting in gas velocities faster than the speed of sound. After the cracking temperature has been reached, the gas is quickly quenched to stop the reaction in a transfer line heat exchanger or inside a quenching header using quench oil.

A higher cracking temperature (also referred to as severity) favors the production of ethene and benzene, whereas lower severity produces higher amounts of propene, C4-hydrocarbons and liquid products. The process also results in the slow deposition of coke, a form of carbon, on the reactor walls. This degrades the efficiency of the reactor, so reaction conditions are designed to minimize this. Nonetheless, a steam cracking furnace can usually only run for a few months at a time between de-cokings. Decokes require the furnace to be isolated from the process and then a flow of steam or a steam/air mixture is passed through the furnace coils. This converts the hard solid carbon layer to carbon monoxide and carbon dioxide. Once this reaction is complete, the furnace can be returned to service.
\[ - \frac{d[C_3H_8]}{dt} = k \cdot [C_3H_8]^{3/2} \]

Pyrolysis of Ethane

Pyrolysis of Propane
The proportions of products depend on the feedstock and on the cracking conditions in the furnace, such as temperature, pressure and residence time.

Typical product yields (%) by mass from steam cracking various hydrocarbon feedstocks.

*RPG (= raw pyrolysis gasoline) is a mixture of C5 - C8 hydrocarbons. RPG is selectively hydrogenated, then aromatics (benzene, methylbenzene and dimethylbenzenes/BTX) are removed by solvent extraction and the residue is used as fuel, e.g. for petrol blending.*
In most of the pyrolysis reactors (furnaces), particularly tubular reactors, the temperature is not a permanent, but constantly growing from input to output of the reaction coil (pipe). With the change of temperature, reaction rate also changes, usually determined by the average value of the rate constant (\( \int k \)) and its product over time. The value of this multiplication can be calculated from the value of the conversion (X):

\[
\int k \cdot dt = k \cdot t = 2,3 \log \left( \frac{1}{1 - X} \right) = KSF,
\]

KSF - kinetic severity function.

Its value directly affects the yield of the product, and its high value increases the share of aromatic hydrocarbons and coke.

Areas during decomposition of naphtha:

Zone 1: KSF < 1; the primary reaction
Zone 2: KSF 1···2.5; primary and secondary reactions
Zone 3: KSF > 2.5; secondary reactions + coke formation
Mass balances in the pyrolysis process of gasoline for capacity of 500,000 t ethylene per year (in 1000 t)

|-------------------------------------|----------------|
| Butadiene (50)                      |                |
| Isobutene (44)                      |                |
| Butene (30)                         |                |
| Butane (14)                         |                |
The total process of pyrolysis of hydrocarbons, depending on the type of feedstock (C/H ratio), reactor design and separation processes, are classified into the following sections:

1) **Pyrolysis**
   a) process in tubular reactor
   b) process in a fluidised-bed reactor.

2) **Separation - product separation.**

Pyrolysis processes are carried out with the addition of water vapor in the volume share (%) which increases with increasing molecular weight of raw material:

- ethane (25%), propane / butane (30%), naphtha (35%) and gas oil (50%)

The effect of water vapor in a mixture of hydrocarbons has several advantages and the most important are:

- reduces the partial pressure of CH, and on that way the balance shifts towards ethylene formation, which allows a higher temperature processes with significantly smaller number of side reactions, especially the formation of coke,
- a source of heat and is easier to maintain isothermal conditions of the process, because it posses many times greater thermal conductivity in comparison with hydrocarbons,
- prevents the deposition of coke on the reactor walls:

\[ \text{C(choke)} + \text{H}_2\text{O} \rightarrow \text{CO}_2 + \text{CO} + \text{H}_2 \]

which facilitates heat transfer, because the coke thermal insulator.
During the process of pyrolysis, acetylene and methylacetylene occurs. Their are usually found in the product at the concentration from 0.5 to 3 %, and since they are harmful to the polymerisation process of ethylene, the share of acetylene must be less than 5 mg kg⁻¹.

Therefore, prior to the separation of ethylene, acetylene need to be removed by introduction of the reaction mixture in a separate reactor in which partial hydrogenation of acetylene to ethylene take place (Pd as catalyst, at around 100 °C):

\[
\text{CH≡CH} \xrightarrow{\text{H}_2/\text{Pd}} \text{CH}_2=\text{CH}_2
\]

Substituted acetylenes with higher boiling point, especially methylacetylene (propyne) are fully hydrogenated before separation of propylene, also in a separate reactor:

\[
\text{CH}_3-\text{C≡CH} \xrightarrow{\text{H}_2/\text{Pd}} \text{CH}_3-\text{CH}_2-\text{CH}_3
\]
Process in tubular reactor
The most common process of hydrocarbons pyrolysis since its designed for pyrolysis of lower hydrocarbons - the most commonly used materials such as ethane, propane / butane, gasoline, gas condensate, etc. The reactor is called **pyrolysis furnace**.

It is important to ensure that the feedstock does not crack to form carbon, which is normally formed at this temperature. This is avoided by passing the gaseous feedstock very quickly and at very low pressure through the pipes which run through the furnace.

There is however, a problem; if the plant is run at sub-atmospheric pressure, there may be a leak that allows air to enter into the gases and form an explosive mixture. This is prevented by mixing the feedstock with steam. The steam also acts as a diluent and inhibits carbonisation.

This endothermic reaction occurs in less than a second as the hydrocarbon mixture passes through tubes within the radiant section of the cracking furnace.
The gases (ethane, propane or butane) or the liquids (naphtha or gas-oil) are preheated, vaporised, mixed with steam and then converted to low relative molecular mass alkenes (plus by-products) by thermal cracking at 1050-1150 K in a tubular reactor.

Inside a tubular reactor (pyrolysis furnace) being used for steam cracking naphtha.

The temperature is about 1150 K.

Pyrolysis Furnaces
PYROLYSIS FURNACE CHALLENGES

- Lack of visibility to coking rate
- Environmental impact, energy efficiency, and production stability depend on good combustion control
- Process variability in steam/hydrocarbon ratio control has an adverse effect on yield and coking rate
- An emergency shutdown brings risk of thermal shock
- Hotspots and temperature spikes result in shorter furnace run lengths
- Low fuel temperature and inconsistent composition can cause liquid carry-over and tip plugging
- Low NOx burners are a maintenance challenge
- Improperly performing effluent analyzer can lead to over-cracking, which can reduce desired yield
- Spalling, malfunctioning instruments, and control upsets cause spurious trips
Process in fluidised-bed reactor
It is suitable for pyrolysis of higher hydrocarbons containing "heavy" materials such as gas oil, petroleum distillation residues and other heavy materials.

Pyrolysis process of gas oil in fluidised-bed reactor:
1 – reactor with hot fluidised particle carriers, 2 – regenerator (coke removal), 3 – cyclone
The product mixture from the furnace is cooled rapidly (quenched) to prevent loss of valuable products via side reactions. The products are separated in a complex process involving cooling, compression, absorption, drying, refrigeration, fractionation and selective hydrogenation.

A steam cracker is one of the most technically complex and energy intensive plants in the chemical industry. It has equipment operating from 100 K to 1400 K and near vacuum to 100 atm. Whilst the fundamentals of the process have not changed in recent decades, improvements continue to be made to the energy efficiency of the furnace, ensuring that the cost of production is continually reduced.

The proportions of products depend on the feedstock and on the cracking conditions in the furnace, such as temperature, pressure and residence time.

Product yields/\% by mass from the steam cracking of naptha.

The products from steam cracking include a mixture of C1 - C4 hydrocarbons and are separated by fractional distillation. Some of the columns are:

1. A debutaniser which separates the C4 hydrocarbons from the C1 - C3 hydrocarbons
2. A depropaniser which separates out the C3 hydrocarbons
3. A deethaniser which separates out the C2 hydrocarbons
4. A demethaniser which separates out the methane
5. A C3 splitter which separates propene from propane
6. A C2 splitter which separates ethene from ethane
The **petrochemical industry** produces various kinds of chemical products such as polymers, fibers or rubber, from such raw materials as petroleum, LPG, natural gas and other hydrocarbons through many different production processes. Hydrocarbons, the source material, are used to produce a variety of components including ethylene, propylene, butadiene and pyrolysis gasoline through non-catalytic thermal decomposition reaction with steam (steam cracking). The feedstock to ethylene process varies depending on the availability of resources in each country. For example, in Japan, naphtha (crude gasoline) produced by refining crude oil is often used. In recent years, many ethylene plants that use light gas as a feedstock which comes from refinery and natural gas plant are being built in Middle East. When light gas is used as a feedstock, products other than ethylene are produced in smaller quantities, which leads to plants that produce propylene by dehydrating propane also being constructed. The petrochemical industry is wide-ranging, creating a variety of chemical products.
Ethylene and its derivatives

Ethylene is sometimes known as the "king of petrochemicals" because more commercial chemicals are produced from ethylene than from any other intermediate.

This unique position of ethylene among other hydrocarbon intermediates is due to some favorable properties inherent in the ethylene molecule as well as to technical and economical factors. These could be summarized in the following:

- Simple structure with high reactivity.
- Relatively inexpensive compound.
- Easily produced from any hydrocarbon source through steam cracking and in high yields.
- Less by-products generated from ethylene reactions with other compounds than from other olefins.

Ethylene reacts by addition to many inexpensive reagents such as water, chlorine, hydrogen chloride, and oxygen to produce valuable chemicals. It can be initiated by free radicals or by coordination catalysts to produce polyethylene, the largest-volume thermoplastic polymer. It can also be copolymerized with other olefins producing polymers with improved properties. For example, when ethylene is polymerized with propylene, a thermoplastic elastomer is obtained.

- Ammonia
- Di- and triethylene glycols
- Alcohol or alkyl phenol
**Ethylene and its derivatives**
Ethylene is one of the most important fundamental chemicals in the petrochemical industry as it is the source material for a variety of products such as polyethylene resin, ethylene glycol, vinyl chloride resin, acetic acid, styrene, and alpha olefin which are produced by polymerization, oxidation, alkylation, hydration, or the addition of halogen.
Ethylene – most important products: chemicals and polymers

- Polyethylene: PE-LD, PE-HD, PE-LLD

- Chlorination: $\text{Cl}_2 \rightarrow \text{CH}_2\text{Cl} = \text{CH}_2 \text{Cl} \rightarrow \text{CH}_2\text{Cl} = \text{CHCl} \rightarrow \text{PVC / poly(vinyl-chloride)}$

- Oxidation: $\text{O}_2$, 250-300°C

- Polymerization: $\text{PdCl}_2/\text{CuCl}_2/\text{HCl}$

- Acetaldehyde: $\text{CH}_3\text{CHO}$

- Vinyl acetate: $\text{CH}_2=\text{CH} = \text{CH}_2\text{OOC} \rightarrow \text{PVAC / poly(vinyl-acetate)}$

- Styrene: $\text{H}_2\text{C} = \text{CH}_2$

- Ethylene oxide: $\text{HOCH}_2\text{CH}_2\text{OH}$

- Ethylene glycol: $\text{HOCH}_2\text{OH}$

- Ethanol: $\text{CH}_3\text{CH}_2\text{OH}$

- Ethyl chloride: $\text{CH}_3\text{CH}_2\text{Cl}$
Propylene and Its Derivatives
Propylene is used to produce polypropylene resin, acrylonitrile, acrylic acid, propylene oxide, isopropyl alcohol, and acetone through polymerization, oxidation, alkylation, hydration and the addition of halogen.
Propylene is as important a basic chemical in the petrochemical industry as ethylene.
Propylene production:
- by steam cracking / pyrolysis 65%
- from refinery gases (FCC) 30%
- propane dehydrogenation 5%

Most important propylene derivatives / products

- polypropylene (PP)
  \[ \begin{align*}
  &\text{CH}_3 \\
  &\text{CH}_2=\text{CH} \rightarrow \\
  &\text{CH}\underbrace{\cdots\text{CH}}_n
  \end{align*} \]
  (50%)

- propylene oxide
  \[ \begin{align*}
  &\text{H}_2\text{C} \text{CH}\text{CH}_3 \\
  &\text{O}
  \end{align*} \]
  (10%)

- acrylic acid
  \[ \begin{align*}
  &\text{CH}_2=\text{CH} \text{COOH} \\
  &\text{H}
  \end{align*} \]
  (5%)

- acrylonitrile
  \[ \begin{align*}
  &\text{CH}_2=\text{CH} \text{CN} \\
  &\text{H}
  \end{align*} \]
  (13%)

- oxo-alcohols (2-ethylhexanol)
  \[ \begin{align*}
  &\text{CH}_3\{\text{CH}_2\}_3\text{CHCH}_2\text{OH} \\
  &\text{CH}_2\text{CH}_3
  \end{align*} \]
  (10%)

- isopropanol
  \[ \begin{align*}
  &\text{CH}_3 \text{CHCH}_3
  \end{align*} \]

- epichlorohydrin
  \[ \begin{align*}
  &\text{H}_2\text{C} \text{CHCH}_2\text{Cl} \\
  &\text{O}
  \end{align*} \]

- oligomers
  \[ \text{(C}_3\text{H}_6)_3, (C}_3\text{H}_6)_4 \]

- cumene
Hydrocarbons with four C-atoms, primarily butane, butene and butadiene, are derived from three main sources:
- from natural gas and oil
- steam cracking of higher hydrocarbons
- from refinery gases

Schematic representation of production of C4-hydrocarbons
C4/C5 fractions and its derivatives
Using naphtha as a raw material, an ethylene plant produces highly reactive materials in C4 (BB) fractions or C5 fractions as by-products. Butadiene in the C4 fractions and isoprene in the C5 fractions in particular, are useful chemicals as they are used to produce synthetic rubber such as tires for cars.
The most important products based on C₄-hydrocarbons

Butadiene is mostly converted into Styrene Butadiene or Styrene Butadiene Rubber (SBR) more well known as synthetic Rubber.
Polyybutadiene is also used in tyres and can be used as an intermediate in the production of acrylonitrile-butadiene-styrene (ABS).
ABS is widely used in items such as telephones, computer casings and other appliances.
Aromatics and Its Derivatives

Using naphtha as a raw material, an ethylene plant produces aromatic derivatives (BTX fractions) such as benzene (B), toluene (T), and xylenes (X) as cracked gasolines.

Of the BTX fractions, benzene and xylenes are particularly used in large quantities in general-purpose resins and fibers after being processed with polystyrene, caprolactam, and terephthalic acid.

Since cracked gasolines produced from ethylene plants only are not enough to meet the demand for these products, supply from reformulated gasolines in the oil refining industry is increasing.
Chemicals from cycloaliphatic compounds and from aromatic compounds

- Benzene, toluene, xylenes, ethylbenzene
- xylenes
- o-xylene
- m-xylene
- p-xylene
- phthalic anhydride
- isophthalic acid
- terephthalic acid
- *or methyl esters
- Nitrotoluenes
- Reduction
- Toluenediamine
- Toluene disocyanate
- Bisphenol
- Phenol
- Epoxy resins
- Phenolic resins
- Nonylphenol
- Detergents
- Decylbenzene
- Polymers
- Styrene
- Ethylene
- Propylene
dehydrogenation
- Cumene
- Ditolylethane
- Vinyltoluene
- Hydroperoxide
- Acetone
- Sulfonation and alkali fusion or chlorination and hydrolysis
- Propylene trimer
- Formaldehyde, urea
- Epichlorhydrin
- Caprolactam
- Hexamethylenediamine
- Adipic acid
- Cyclohexanol, cyclohexanone
- Hydroxylamine, acid
- Air
- Nitric acid
- Existing aromatics
- Reforming of cyclopentanes, cyclohexanes, and paraffins
- Refinery naphthas
- Cyclolane
- Air
- Nitric acid
